

# ISF Simulation in Cadence (Transient Analysis)

$$h_q(t, \tau) = \frac{\Gamma(\omega_0 \tau)}{q_{\max}} u(t - \tau)$$

$$\Rightarrow \boxed{\Gamma(\omega_0 \tau) = \frac{\Delta t}{T_0} \cdot 2\pi \cdot \frac{q_{\max}}{\Delta q}}$$

- 1)  $\Delta q$  should be  $\begin{cases} \text{not too small} \rightarrow \text{numerical error} \\ \text{not too large} \rightarrow \text{nonlinearity} \end{cases}$
- 2)  $\Delta t$  should be measured after amplitude settles down. (steady state solution)
- 3) Impulse should be injected after oscillator stabilizes.
- 4) Step size in  $\Delta t$  should be small.
- 5) Transient sim. error tolerance should be small.

## SIMULATION PROCEDURE

Step 1) Setting the Transient time step

Time step : Default :  $\frac{t_{\text{transient}}}{1000} = 10 \text{ pS} \approx \frac{T_0}{10}$

Need at least  $\frac{T_0}{1000} \approx T_{\text{step}} = 100 \text{ fS} \rightarrow 10 \text{ fS to be conservative.}$

## Step 2) Setting Impulse location & $T_{max}$ .

- i) look at freq function to find steady state.
- ii) Look at cosine difference spectrum to verify steady state. (make sure to clip the signal).
- iii) Plot freq function of cosine difference to find  $T_{probe}$ .

$T_{pulse}$  &  $T_{probe}$  are set

Sim Setup TEST {

$$\begin{aligned}\cos(x) - \cos(x - \phi) &= \cancel{\cos(x)} - \cancel{\cos x} \overset{\nearrow \frac{1}{\sin \phi}}{\cos \phi} - \sin x \sin \phi \\ &\approx -\phi \sin x \\ &= \boxed{-\phi \sin(\omega_0 t)}\end{aligned}$$

↳ indicates a stable phase shift.

- iv) Use cross function to find zero crossing when impulse is ~~off~~ <sup>on</sup>. Set significant digits to 16 & note down value.

$$T_{i=0} = 15.62239156 e^{-9} = 15.622 e^{-9} + 0.39156 e^{-12}$$

- > Subtract it from cross output. AOE output truncates it so break it up into different unit scales.
- > Check that out is  $\approx 0$  before running sweeps.

Step 3) : Testing the linear response range.

$$q_{\max} = V_p^{\text{diff}} \times C_{\text{out}} = 580 \text{ mV} \times 145 \text{ fF} \\ = 84.1 \text{ fC} \approx 10^{-13} \text{ C}$$

$\Rightarrow \Delta q$  should be less than  $\frac{q_{\max}}{10^2} = 10^{-15} \text{ C}$

$$\Delta q = I_{\text{pulse}} \cdot \underbrace{\Delta t_{\text{pulse}}}_{T_0/100} = \underbrace{I_{\max}}_{\substack{1 \text{ mA} \\ \text{Set to } 1 \mu\text{A}}} \times \underbrace{1 \text{ pS}}_{10^{-12}}$$

Step 4) : Simulate ISF by sweeping impulse location over 1 period.
